Chapter 1: Introduction

Purpose of the Study

Teaching science is a challenging task because the majority of science labs are interactive in which students manipulate and move things around in order to better understand the concepts being taught. Finding and utilizing appropriate labs for simpler concepts such as metals vs. non-metals or identifying rocks and minerals is fairly easy. However, the search for and use of appropriate labs is more challenging when teaching lessons of concepts that are of a more intangible nature. Concepts and lessons about the solar system, universe, or molecules are examples of such. For these, there is a lack of available hands-on activities which often requires the use of computer simulations. The purpose of this study was to examine ways of pairing computer simulations and hands-on activities in science instruction to create successful, engaging lessons.

To aid in student understanding, teachers often use a number of techniques such as analogies, inquiry-based activities, and technology to help the students understand and retain the content. Teachers have found that computer simulations have greatly increased a student's ability to understand key concepts which are largely intangible (Podolefsky, Perkins, & Adams, 2010).

Often, the quality of a lesson hinges on the quality of the simulation. For example, if a simulation only allows the users to click on links that provide them with an animation or picture with information, it can be used as an introductory lesson. This kind of simulation provides students with a more traditional learning experience. Sometimes computer simulations can be

more useful if students have concepts presented to them prior to doing the simulation, depending on the complexity of the content.

A simulation can also allow a user to manipulate a number of variables that produce different outputs; this kind of simulation is used as an inquiry-based lesson. Computer simulations that are used as an inquiry lesson allow the student to digitally manipulate a number of variables that produce different results. Inquiry-based lessons are similar to hands-on activities in that they both provide the student opportunities to change variables.

Many times it is beneficial to pair inquiry-based computer simulations with hands-on, inquiry-based, real life activities. Research conducted by Eskrootchi and Oskrochi (2010) and Kim (2006) suggests that pairing in this way significantly affects students' understanding of the concept. Though the research done on this topic is rather sparse, the findings do suggest a positive impact on classroom learning.

Research Question

What is the most effective way to pair computer simulations and inquiry-based learning activities in an eighth grade Earth Science class?

Rationale

My source of information is ERIC. I searched for full text journals published from the year 2000 to the present date.

Search terms used:

- Educational Technology
- Technology
- Computer Simulations

- Simulations
- Secondary Science Education
- Earth Science
- Inquiry-Based Learning

While researching in ERIC, the xyz database included a number of articles that focused on computer simulations in science instruction at the post-secondary and graduate levels. These studies often used very complex computer simulations that addressed very complex physics and chemistry content. Many studies focused on the use of computer simulations in the work place in order to increase quality of employee training for companies. A number of studies have also been completed on the effect of computer simulations at the primary level of education. I limited my search to the middle school level of education and focused on research that was done in science classrooms, due to it being most pertinent to the research question posed in this paper.

While researching, I found very few articles from years prior to the 2000s pertaining to computer simulations. This is likely due to the fact that this is a very new area of interest. The studies of focus used adequate sample sizes, with all sample sizes being between 2-4 class sizes, and were closest to the grade level and subject that I teach. Also favored were articles that addressed student attitudes prior to and after the study was completed.

Definition of Terms

Computer simulation: a computer simulation or a computer model is a computer program that attempts to simulate an abstract model of a particular system.

Educational technology: the study and ethical practice of facilitating learning and improving performance by creating, using, and managing appropriate technological processes and resources.

Inquiry-based learning: a form of active learning where progress is assessed by how well students develop experimental and analytical skills rather than how much knowledge they possess.

Digital natives: a person born and raised during the age of digital technology and therefore familiar with computers and the Internet from 1990s to present.

Technology: the application of scientific knowledge for practical purposes.

PhET: a suite of research-based interactive computer simulations for teaching and learning physics, chemistry, math, and other sciences.

STELLA: a flexible computer modeling package with an easy, intuitive interface that allows users to construct dynamic models that realistically simulate biological systems.

Chapter 2: Literature Review

Twenty first century teachers differentiate their teaching strategies from their predecessors by using technology in their classroom in order to improve student learning. Below is a review of studies that focus on inquiry-based learning practices and the use of computer simulations in the science classroom. The focus of this chapter is on how computer simulations are being paired with hands-on inquiry-based learning activities to provide the student with a positive learning experience.

Inquiry-Based Learning

Inquiry-based learning encourages students to discover information as an alternative to teachers dispensing the information directly to them. The 5E Instructional model is a model that aids teachers in the building of an inquiry-based lesson that has been developed and used by science teachers (Bybee, 2014; Bybee & Landes, 1990). Duran and Duran (2004) summarized the five steps or phases of the 5E learning cycle as well as addressed how each phase is used.

The 5E Instructional Model is broken into five phases of learning: Engagement, Exploration, Explanation, Elaboration, Evaluation.

- Engagement:
 - This phase is aimed at addressing student's prior knowledge and is a motivational period that pushes the student to want to learn about the content.
- Exploration:
 - This phase encourages students to explore by making observations, questioning, investigation, hypothesizing, testing hypotheses, and communicating their results. This phase is where the main inquiry-based lesson is performed.

- Explanation:
 - This phase allows students to describe their understanding of the content, after it is learned in the exploration phase. The teacher becomes more of a facilitator providing guiding questions that enable the students to form their own explanations. This is also a time when the teacher introduces scientific information in a direct manner by giving formal definitions and notes.
- Elaboration:
 - This phase requires students to use the information learned in the explanation phase and apply it to new situations or scenarios. During this phase students will design new experiments or models and communicate their understandings with peers. This phase often encourages students to integrate what they have learned with other content areas.
- Evaluation:
 - The evaluation of student progress is very different when compared to traditional lessons. Inquiry-based assessments look for continual progress in a student's learning, looking for the students understanding of new concepts and skills as well as evidence to show that a student has changed their thinking.

through traditional instruction methods or inquiry-based learning activities. The experimental group was given a project that was built using the 5E learning cycle. In the Experimental group, students were given the opportunity to observe microbes under a microscope, ask questions, form a hypothesis, and test their hypothesis. Students then developed explanations of what they found. The teacher guided the students to help the students develop more coherent explanations. Students were then asked to elaborate on their ideas, which required them to do further research into vaccines and how they work. Students were then evaluated on their understanding of the content through achievement tests.

The control group received a traditional approach to the lesson. This approach included direct question and answer methods driven by the teacher; the students were given less autonomy in this group. In order to teach the concepts, students were provided instruction through lecture and discussion, notes written on the blackboard, and worksheets for students to complete. All students were taught by the same teacher and were randomly selected by an administrator and put into the teachers classes. The textbooks and handouts were exactly the same for both the experimental and control groups. The duration of this study was 8 weeks.

Abdi (2014) used a mean, standard deviation, and one-way ANCOVA to analyze their data. Below is a table showing the results of the study.

Table 1

Means, Standard Deviations, and Standard Error Mean of the Experimental and Control Groups for Pretest and Posttest Scores in Academic Achievement Test

Variable	Group	N	Mean	Standard Deviation	Standard Error Mean
Pre-test	experimental	20	3.15	1.461	.327
	control	20	2.95	1.538	.44
Posttest	experimental	20	7.30	.979	.219
	control	20	6.35	1.226	.274

Table 2

ANCOVA Analysis for the Differences in Posttest Mean Scores Between Experimental and Control Groups in Academic Achievement Test

Source	Sum of Squares	df	Mean Square	F	Sig.
Pre	2.327	1	2.327	2.056	.160
Group	5.796	1	5.796	5.121	.030
Error	40.743	36	1.132		
Total	1919.000	40			

The experimental group had a mean square of 5.796 and a significance of .03. The data collected shows that there is a significant difference between achievement tests of the two

groups. Overall the study found that those who were taught using an inquiry-based style (5E learning cycle) were more successful on the achievement tests than those who were taught using a traditional method. This could mean the students have a greater understanding of the material if taught using the 5E learning methods.

This research was conducted with a small sample size, which is a limitation of this study. A larger sample may provide more reliable results in the future. In addition, a pre- and post-survey of student attitudes toward the two teaching methods may have provided more support for inquiry-based lessons and their impact on student achievement levels.

Educational Computer Simulations

The use of technology has become an increasingly popular way to facilitate student learning. Since the 1980s, technology has greatly enhanced learning for students today, largely due to the way these students learn (Prensky, 2001). Children born after the 1980s are considered to be the “digital natives” of our world, often spending more time playing video games, checking email, surfing the web, and texting than generations before them (Prensky, 2001).

In today’s science class, the use of Internet driven computer simulations can address a complex idea. Concepts such as states of matter, atoms, chemical reactions, plate tectonics, and lunar phases are difficult to teach without the use of a computer simulation, simply because the ideas being taught occur on such a large or small scale and they can sometimes be more abstract. Because Internet driven computer simulations can address complex ideas, they challenge students to think critically about these abstract concepts.

Climatologists use computer simulations or models to analyze changes in a particular climate. Meteorologists also use simulations to predict weather a week in advance. These computer simulations use a set of data and variables of local/regional cities to paint a picture of a potential future. An educational computer simulation is designed in a similar way. The simulation is a computer program that allows users to change a particular set of variables or parameters, which then builds a virtual environment using those variables or parameters. Because of this, computer simulations have been able to be very engaging for students, provided the student is the one asking the questions and driving the investigation.

Adams, Paulson, and Wieman (2008) and her team's results from their research support this idea. Reid et al. (2008) and Podolefsky, Perkins, and Adams (2010) did similar research and had similar results. Adams' team conducted over 250 think aloud style interviews with 100 student volunteers. Students were interviewed multiple times throughout the simulation. The think out loud interviews were not set up to ask for the students opinions or feedback of the simulation, rather they were focused on how the participant thought out loud throughout the experience. This allowed researchers to see how the participant was thinking throughout the simulation. There were four to six interviews, lasting 30-60 minutes, conducted for each simulation and all were videotaped to allow for a deeper analysis of the evidence. There were four different types of interviews, or levels of guidance, and each type were created as an independent variable. The four types were as follows:

- Type A: No instruction
 - No instruction was provided to the participant. Open “play” of the simulation was allowed. The participant was allowed to do whatever they felt like doing in the simulation
- Type B: Guided questions
 - There was some guidance provided by the teacher but it was limited to a few guided questions that gave the participant more of a sense of direction and specific things to look for during the investigation.
- Type C: Gently guided
 - In this type, participants are asked questions about particular functions of various buttons in the simulations before they can move on to the next step in the simulation. This type of guidance allows for some minor learner exploration, but does not foster the student’s drive to explore as much as types A and B because there are specific factors the instructors are focusing the students’ attention on, rather than letting them explore more freely as in types A and B.
- Type D: Strongly guided
 - A step by step guidance through the simulation. The participant is not able to do any exploration of the simulation. These questions are typically set up as “First do this, second do this, third do this, etc...”

The website used was PhET (Physics Education Technology) which provides over 80 highly inquiry-based computer simulations that address all or many areas of science as well as many from math. Other studies using PhET simulations found that these simulations have

dramatically increased student understanding of the physical world by allowing students to take control over the simulation to manipulate the variables (Moore, Chamberlain, Parson, & Perkins, 2014; Perkins, Moore, Podolefsky, Lancaster, & Denison, 2012).

Adams et al. (2008) found the participants that had experienced types A and B had gained physical insights into the ideas presented in the simulation by their ability to ask their own questions. This allowed them to have control over where they were going throughout the simulation. They also found that students who were told the answers, or who were strongly guided, were not able to develop the framework necessary for solving future problems in the content area.

The research team also found that the type of interview and the complexity of the simulation played a very important role in the participant's ability to work through it. If the simulation was too complex and the participant was given type A or B guidance, researchers found that the participant was less likely to complete the simulation, oftentimes giving up or losing interest. They found that participants with type C guidance benefited more during a complex simulation. Analysis of the video and audio collected showed that students with type C guidance were able to build a better framework of the concepts at hand due to being able to explore on their own with little guidance.

Research completed by Podolefsky et al. (2013) also supported Adams et al. (2008) research which showed that students need to be in control of their learning. Podolefsky et al.'s (2013) research was focused on the amount of time a student was allowed to play with the simulation prior to doing the assignment and how well the students were able to work through the simulation based on the type of questions that were being asked by the teacher. The

simulation used was a PhET simulation called “Bending Light.” Researchers used two fifth grade science classes, one class had eight students (experimental group) and the other had five students (control group). The experimental group was allowed 8 minutes of free play at the beginning of the simulation and the control group started the simulation right away.

To collect their data, researchers used a video camera to record the classroom as students worked as well as software called Camtasia, which allowed researchers to record all of the student’s computer screens while they were working through the simulation. The research team also used microphones that were built into the computers to record student voices. The researchers recorded students every 15 seconds throughout the time period. In order to effectively quantify and organize the data, they created codes to signify the type of teacher questioning that was happening throughout the period, TOQ stands for Teacher Open Question and TCI stands for Teacher-Centered Question. Doing this allowed them to sort through and understand if students were using the simulation during or after teacher questioning and to quantify the different kinds of questions being asked (TOQ or TCI). This was also paired with microphone recordings which allowed researchers to understand how the students worked their way through the simulation.

After analyzing the data, researchers found that the students who had more play time at the beginning had more time using the simulation throughout the class period. When students were allowed more play time, they found that the number of teacher evoked questions to the class were dramatically reduced. In addition, the teacher led discussions throughout the lesson were high quality discussions, as determined by the teacher through the amount of student engagement during the discussions. This is an indicator that the scientific concepts addressed in

the simulation were being understood. The class that did not have play time at the beginning had less time, overall, working with the simulation and had a difficult time working through the simulation. There was found to be more teacher redirection throughout the time period and the discussions led by the teacher did not have the quality that the play group had due to the students inability to understand the scientific principles.

Researchers concluded that if the teacher gives the student 5-10 minutes of play time prior to doing the simulation, students tend to feel as though they have more ownership over the simulation and because of that will have a more productive experience during the simulation. A limitation to this study is that the sample size was very small. Despite the small sample, the results still strengthen the theory that computer simulations and instruction that is built with the philosophy that the student is at the center of his or her learning will provide the student with the most learning. Also, to better quantify their data, the researchers could have utilized a pre- and posttest to better understand student progress with the scientific concepts and possibly student attitudes about the activity.

Other types of computer simulations can be utilized in more technologically advanced ways. The use of 3D virtual reality simulations have been successfully used in the classroom (Kim, 2006). A study was done on fifth grade earth science students during a plate tectonics unit (Kim, 2006). It focused on the comparison of a 3D virtual reality simulation and a traditional 2D simulation and how they affect student's achievement on test scores as well as how their attitudes toward science changed from the beginning to the end of the study. In order to test this, pre- and posttests were given, measuring student achievement as well as surveying students in order to measure student attitudes toward science.

Two groups were selected, a 2D group and a 3D group. The 2D group was designated as the control group with 20 students. The 3D group was the experimental group and contained 21 students. Gender and ethnicity were noted and no prior information about the content was taught before the simulation.

During the study, both groups of students engaged in observing the same types of phenomena (volcanoes, earthquakes, movement of tectonic plates, etc.) but in different ways. The 3D group used a dual projection system to create a three dimensional effect which allowed them to manipulate aspects of each concept. The 2D group used the same simulation but experienced it in only two dimensions.

Table 3

Means and Standard Deviations of Test Scores and Attitude Mean Scores by the Type of Lessons

	Mean	Standard Deviation
Test Score:		
Before Lesson		
2D	22.00	11.96
3D	30.95	23.43
After Lesson		
2D	33.05	16.94
3D	50.00	22.36
Attitude:		
Before Lesson		
2D	2.70	0.30
3D	2.86	0.67
After Lesson		
2D	2.74	0.59
3D	3.02	0.54

The table below shows a one-way ANOVA of the pre and posttests of both student achievement and attitudes about science. The data shows that the 3D group had a statistically significant increase, from 30.95 points to 50 points, in student achievement when compared to the 2D group, which saw an increase from 22 points to 33.05 points. Also, both groups did not see a significant change in attitudes about science and there was no significant difference in achievement between genders and ethnicities.

Researchers concluded that the 3D group had a statistically significant increase in achievement test results when compared to the 2D group. This is thought to have happened due to the highly interactive and immersive learning environment that was created by the 3D effects. There was no significant difference of achievement between genders or ethnicities.

Computer Simulations and Inquiry-Based Learning Activities

Inquiry-based learning allows for the learner to take control over what they are learning in a hands-on, student led fashion. Taking this philosophy and incorporating it into a computer simulation can allow for an even greater enhancement of learning. However, when you pair computer simulations and hands on, inquiry-based, learning activities together, research shows that it may or may not increase learning (Roseman & Jones, 2013).

Roseman and Jones (2013) researched the effectiveness of computer simulations compared to hands on learning activities when teaching about lunar phases. They tested 130 seventh grade earth and space science students. Each student was given a modified version of the Lunar Phases Concept Inventory (LPCI) as a pre- and posttest. The LPCI is a multiple choice assessment that was modified in its length (down to 12 questions) and in the number of possible answers (down to 4), as it was originally designed to assess higher level students in

more advanced classes. The assessment was also modified to be in accordance to federal law for students who have an IEP (Individualized Education Plan), in which case these students were given fewer possible answers.

All students received the same material and were given an introduction to lunar phases and were given pretests. The researchers then split the students into two groups of 65 through random selection of entire classrooms. One group received information through hands on learning activities. This group received a Styrofoam ball that represented the moon, the earth was represented by a student's head, and a light was placed at the center of the room to represent the sun. The students were then asked to revolve around the sun to make the different phases of the moon.

The second group looked at a computer simulation that contained three scenarios. The first scenario required the student to show which side of the moon was lit up by the sun. The second scenario asked that they correctly identify the phases of the moon. The third related the phases of the moon to a complete orbit around the earth. A posttest was given after the completion of the activities.

The results of the pre- and posttest below showed that there was no statistically significant difference between the hands on activity and the computer simulation. Although, researchers noted that there was a slightly larger increase of scores for the pre- and posttest in the hands on group, but the increase was not statistically significant. There was a statistically significant difference between students with IEP in the two groups, showing that hands on activities may benefit these students more compared to computer simulations..

Qualitative data was also collected in the form of field notes and documented observations. Researchers found that during the pretest, students tended to close their eyes and visualize with their hands, using them to model the moon as it revolved around the earth and presumably what the moon looked like at night. This was also observed during the posttest. One difference that was noted was that the students who were in the hands on group were orienting themselves, in relation to the sun, in their seats. This was thought to provide a better visual when trying to answer the posttest questions. This behavior was not seen from students in the computer simulation group. Researchers also noticed that some students with IEPs became frustrated with the computer simulation, which could have a negative impact in their understanding of the material.

This study concluded that there was no statistical significance between the hands on group and the computer simulation group. Both activities seemed to have the same increase in test scores. One limitation to this study is that the computer simulation used may not have been an inquiry-based computer simulation, the research did not indicate which simulation was used. Because of that, students in the hands on group may have been provided a more student-centered learning opportunity than those in the simulation group. That could have a major effect on the results of this study.

Roseman and Jones (2013) found that there was no statistically significant evidence to support using hands on activities over computer simulations. But, Eskrootchi and Oskrochi (2010) found that instead of using one method or the other, the pairing of computer simulations and hands-on activities proved to be successful when teaching about watersheds and the use of

water, when compared to more traditional teaching and sole use of simulations to teach material. (Eskrootchi & Oskrochi, 2010)

Eskrootchi and Oskrochi (2010) conducted the study with 72 sixth- to eighth-graders (32 males and 40 females). All students received the same initial information through online sites, collaborating with peers, defining terminologies and using hyperlinks to additional information. All material was delivered by the same teacher. Prior to the study, all students took a pretest that consisted of 58 questions to assess their understanding of watersheds and content knowledge as well as their attitude toward the project. Researchers then randomly split the participants into three groups:

- Project Based (PB): 19 participants
 - Taught content through traditional lecture only.
- Project Based Experimental Simulation (PBES): 33 participants
 - Taught content by performing an experimental model and a simulation model.
- Project Based Simulation (PBS): 20 participants
 - Taught content by a simulation model only.

A lesson on the “effect of land-use on the watershed” was developed using two methods. One method was an experimental model, or hands on method, that used a sponge and cardboard, and the second was a computer simulation called STELLA (Structural Thinking and Experiential Learning Laboratory with Animation) which allowed students to manipulate variables to scenarios that investigate how humans interact with their environment. Two STELLA applications were used. The first application, STELLA1, used data obtained from the experimental model with the sponge and cardboard. The second application, STELLA2, was

more advanced and was created using real data from a watershed. The applications allowed the students to manipulate a number of factors and variables on the watershed.

The results of the study can be found below. A one way ANOVA showed that there was no significant difference between all groups in their content knowledge. However, the student's comprehension knowledge was significantly higher between PBES and PBS (.002) and PBES and Traditional (.000). A Post Hoc test result revealed that the PBES group outperformed the other two groups on comprehension.

Figure 2

Students' Comprehension Gains by Treatments for Male and Female

Treatment (I)	Treatment (J)	Mean (I-J)	Sig.
Project-Based Experimental Simulation	Project-Based Simulation	3.162	.002
	Traditional	4.450	.000
Project- Based Simulation	Traditional	1.294	.692

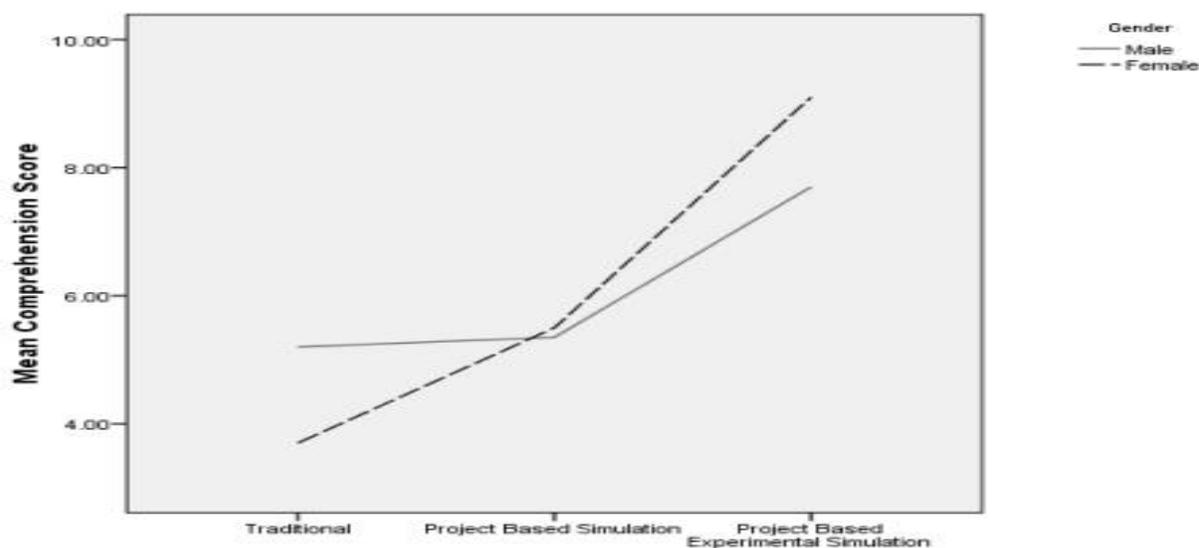

Figure 1: Students' comprehension gains by treatments for male and female

Based on observed means. The mean difference is significant at the .05 level.

The graph on the previous page shows an analysis of the results based on gender between the three groups. The data shows that there no significant differences between the three methods for the males but the females had a statistically significant higher score between the PB and PBES groups. This shows that PBES had a stronger effect on females in that group. An analysis of student attitudes toward the project and STELLA were at 85% favorable. Students felt that STELLA enhanced their understanding about the watershed.

The researchers concluded that even though PBES scored higher than PB, PBS did not. This suggests that computer simulations should not be a replacement for hands on learning activities; rather it should be used as a supplementary tool. Reasons for this could be because students have an increase in the amount of communication with their peers throughout the process. Also, in this case, the hands on activity allowed the students to gather data and build a basic foundation around the content. The computer simulation was used to work with the data on a deeper level, building even more connections with the material.

Chapter 3: Conclusion

I have had the opportunity to teach a variety of subjects within the science field throughout my teaching career. In all subjects, I have relied heavily on computer simulations to help students understand the content. The reason for this was because the content was either too complex to be taught using a hands on activity or I did not have the funds available to carry out the needed activities.

I have often used computer simulations instead of hands-on activities because computer simulations were able to give my students an opportunity to dig deeper in their investigation than a hands on activity would allow for. However, at times I have used hands-on activities. This was because there was a distinct benefit in providing students the opportunity to be able to touch and manipulate real-life objects. I have often wondered about the outcome of research which would focus on various ways to use both computer simulations and hands on activity to get a “best” result, when it comes to student learning. What is the most effective way to pair computer simulations and inquiry-based learning activities in an eighth grade Earth Science class?

Conclusion

In conclusion, there are a number of different kinds of computer simulations used in the science classroom. Inquiry-based learning practices are successful at teaching students complex content. Studies show that students need to be at the center of their learning in order for the lesson to be successful. The student needs to be able to drive their learning or be gently guided by the teacher in order to explore the content on a deeper level.

Computer simulations and hands on activities should be used together as supplementary tools. Eskrootchi and Oskrochi (2010) found that computer simulations should not be used in

place of hands on activities because of the benefits of peer to peer communication and collaboration, as well as it provides a “real” experience where the student is able to use their senses to build a framework around the content. This has been shown to improve the comprehension of scientific concepts.

Recommendation

After reviewing the research, my recommendations are as follows: Instead of replacing hands on activities with computer simulations, the pairing of computer simulations and inquiry-based curriculum is a better approach. Eskrootchi and Oskrochi (2010) found that the pairing of the two enhances the learning of the student and allows them to explore scientific principles on a deeper level. Additionally, teachers should find ways to use both methods to enhance their science curriculum. Third, teachers should also address the type of computer simulations as well. Computer simulations that are built around an inquiry-based philosophy provides the learner with the most enhanced learning opportunities when compared with computer simulations that are built around a more traditional style of learning (information seeking, question and answer type simulations).

Practice

The research done by Podolefsky et al. (2010) was very encouraging because I have tried the same in my classes and had a similar result. Allowing students to play with the computer simulation at the beginning of the period gives students a chance to explore independently. It is similar to someone learning to play a new video game or learning how to operate an iPad. Learning as you go seems to give students control and promotes exploration.

When I found the Podolefsky et al. (2010) research, I knew I wanted to test it in my classroom. I have noticed that if I allow students time at the beginning of class, there are fewer questions throughout the class because they already know how to operate the simulation. There is also a greater degree of frustration from a few of the students when they are not able to understand the controls for the first part of the class. In these instances, I found that I needed to incorporate more guiding questions for these students. Type of questioning was also part of Podolefsky's et al.'s (2010) research. They found that particular types of questioning from the teacher allowed for a better learning experience. I used more of a guided questioning method for the time that I allowed the students to play to alleviate student frustration and prevent them from giving up at the beginning.

Adam et al.'s (2008) research also supported the idea that the least amount of guidance throughout the computer simulation allows the student to form a better framework of the scientific principles. This is also an article that I came across early in my research. I used the findings and incorporated them in a few of the PhET computer simulations (States of Matter, Plate Tectonics, Glaciers) earlier this year and found that it worked for some classes and not for others. I found that for classes that had students with higher academic levels or students who had more experience playing video games tended to do well with as little guidance as possible. Although, the students with the more gaming experience tended to get off track a little more and required more redirection than other groups of students. The classes that had lower academic levels or had students who did not play many video games struggled with the simulation and required more guidance. I plan on continuing to use computer simulations but I will be more mindful of who might need a little more guidance throughout the activity.

There is a lot of research that has been done on the different kinds of computer simulations available to the classroom. There is also a lot of research done on how to effectively implement inquiry-based activities. But there is not a lot of research out there about the use of the two together. I found that Eskrootchi and Oskrochi's (2010) research on the how to incorporate computer simulations into a inquiry-based classroom to be the most informative article I found, when it comes to pairing the teaching methods. Their research shows that computer simulations should not take the place of inquiry-based activities; instead they should be used as a supplementary resource to inquiry-based activities. My practices in the classroom have been different from the recommendations of this research. I have replaced several of my hands on lessons with computer simulations due to the fact that they do a better job at helping the students to understand the material. In the future, however, I will be reincorporating the hands on learning back into my curriculum and using computer simulations as a supplementation to the lesson.

Summary

Teaching can be a challenging task, especially when teaching concepts related to science. Many activities done in a science class are hands on activities where the students manipulate and move things around in order to better understand the concepts at hand. Pairing computer simulations with hands on activities can further enhance learning for the student, allowing them to explore the content on a deeper level.

Ann Landers says it best when she says, "It is not what you do for your children, but what you have taught them to do for themselves that will make them successful human beings."

Teaching the student to take control of his or her own learning and allowing them to explore and

discover on their own, whether it's through hands on learning or computer simulations, is the most important part of the lesson.
